# DAML walkthrough

The main point of interest is `train_maml` in `model.py`.

`prev_min_loss` gets set to a high value on [line 120](#) using bit shifting.

Then we go through epochs. This corresponds to `train()` in `metatrainer.py`.

`Self.training_adjust()` on [line 127](#) just returns? Weird `self.m.self_adjust()` on [line 128](#) is referring to the TSD model in `tsd_net.py`.

This also [just passes](#)? WTH?

line 132 handles the data reading and dumps the result in `turn_batches_domain`.

Lines 134 and 135 declare two optimizers, `optim`, and `meta_optim`. They use a filter expression  
`meta_optim = Adam(lr = self.meta_lr, params=filter(lambda x: x.requires_grad, self.m.parameters()),`  
.

This obtains only the parameters that need gradient updates. I'm not currently doing this step, so this is potentially where my stuff is going awry. I am doing a similar filter [on line 241](#). However, this is filtering the parameters before the model copy happens, not when the optimizer is created.

They then copy the model's state dict using `copy.deepcopy`. I think this is the python internal `deepcopy` mechanism instead of the pytorch specific one.

For batch in data, for each task [get the data](#).

Load the state dict into the model, zero out the gradients on `optim` (I think this is the inner optimizer)

They call `self._convert_batch()` on [line 154](#). Need to look and see what that does but my initial reaction is that it's unimportant and specific to their task setup.

For each step in `cfg.maml_steps` run the input through the model and get the loss, `pr_loss`, `m_loss`

and turn\_states

call `loss.backward()` to get gradients. grab the model parameters and gradient clip them Then step the inner optimizer (optim)

Once out of that loop, run the model again. It says it's using fresh data in the comment on [line 178](#) but as far as I can tell, it is not.

record the losses in an array.

Then outside that loop, identify

# Optimizer filter notes

The DAML implementation uses this filter when constructing the optimizer

```
Adam(lr = self.meta_lr, params=filter(lambda x: x.requires_grad, self.m.parameters()),weight_decay=
```

.

I'm unsure how important this is, but for now, I've hard coded this into the `from_params` for the optimizer and the constructor for the metatrainer (for the `meta_optimizer`).

I need to get a metatrainer working and then figure out how to make it more flexible in the allennlp framework.

# Gameplan

**Done** Switch optimizer over to the ifiltered optimizer.

**todo** determine if `self.model` needs to be modified in the batch\_update section

**todo** make the maml optimizer stepping logic match the logic in daml

# Status tracker

## 2-21-2020:

Finished a bunch of updates to the outer loop of maml to make it better reflect the daml implementation. However, allennlp is telling me

```
from src.data import *
File "./src/data/__init__.py", line 1, in <module>
    from
src.data.tokenizers.word_splitter_additions import \
File
"./src/data/tokenizers/__init__.py", line 5, in <module>
    from
src.data.tokenizers.word_splitter_additions import \
File
"./src/data/tokenizers/word_splitter_additions.py", line 11, in <module>
    from
allennlp.data.tokenizers.word_splitter import _remove_spaces, WordSplitter
ModuleNotFoundError: No module named 'allennlp.data.tokenizers.word_splitter'
```

when I try to run it in `/home/kenneth/Projects/nadapt_12_11/neural-adapt-dev`.

Was there a different location I wanted to use?

There's a different branch `metalearn` that needs to be checked out.

## 2-25-2020:

Every time the maml learner goes through the validation part, the qwk drops to 0. Sometimes it recovers during the epoch but sometimes it does not.
